

Hands-On: Handling Form Input in React

In this lab, you will create a simple React component that handles form input and updates the component's state with the input value.

Step 1: Create a new React component

Create a new file called `Form.js` and add the following code:

```
import React, { Component } from 'react';

class Form extends Component {
  state = {
    inputValue: "",
  };

  handleInputChange = e => {
    this.setState({ inputValue: e.target.value });
  };

  handleSubmit = e => {
    e.preventDefault();
    alert(`You entered: ${this.state.inputValue}`);
  };

  render() {
    const { inputValue } = this.state;

    return (
      <div>
        <h1>Handling Form Input in React</h1>
        <form onSubmit={this.handleSubmit}>
          <label>
            Enter some text:
            <input type="text" value={inputValue} onChange={this.handleInputChange} />
          </label>
          <button type="submit">Submit</button>
        </form>
      </div>
    );
  }
}

export default Form;
```

This component has an initial state with an empty `inputValue` property. The `handleInputChange` method updates the component's state with the input value, and the `handleSubmit` method alerts the user with the input value when the form is submitted. The `render` method renders a form with an input field that updates the component's state and a submit button that triggers the `handleSubmit` method.

Step 2: Render the component

Create a new file called `App.js` and add the following code:

```
import React from 'react';
import Form from './Form';

function App() {
  return (
    <div className="App">
      <Form />
    </div>
  );
}

export default App;
```

This component simply renders the `Form` component.

Step 3: Run the app

Run the app using `npm start` and test the `Form` component by entering some text into the input field and submitting the form.

Congratulations! You have successfully handled form input in a React component.
